Decomposition of Dinitrogen Pentoxide At $45^\circ$C, dinitrogen pentoxide (N$_2$O$_5$) decomposes into nitrous dioxide (NO$_2$) and oxygen (O$_2$) according to the law of uninhibited decay. An initial amount of 0.25 mole of dinitrogen pentoxide decomposes to 0.15 mole in 17 minutes. How much dinitrogen pentoxide will remain after 30 minutes? How long will it take until 0.01 mole of dinitrogen pentoxide remains?\(^1\)

The law of uninhibited decay is

$$A(t) = A_0 e^{kt}$$

so we need to determine the values of $A_0$ and $k$ for the model, and then we can respond to the questions.

The problem states that the initial amount of N$_2$O$_5$ is 0.25 mole; this is the value of $A_0$. Substituting,

$$A(t) = 0.25 e^{kt}$$

Now we’ll substitute the 0.15 mole in 17 minutes, and solve for $k$

$$0.15 = 0.25 e^{k \cdot 17}$$

$$\frac{0.15}{0.25} = e^{17k}$$

$$0.6 = e^{17k}$$

$$\ln(0.6) = \ln(e^{17k})$$

$$\ln(0.6) = 17k$$

$$\frac{\ln(0.6)}{17} = k$$

or

$$k \approx -0.0300$$

Thus the mathematical model for the decay of 0.25 moles of dinitrogen pentoxide is

$$A(t) = 0.25 e^{-0.0300t}$$

After 30 minutes, there will be

$$A(30) = 0.25 e^{-0.0300 \cdot 30}$$

$$\approx 0.1016$$ moles

To find how long until only 0.01 moles remain, we substitute and solve

$$0.01 = 0.25 e^{-0.0300t}$$

$$\frac{0.01}{0.25} = e^{-0.0300t}$$

$$0.04 = e^{-0.0300t}$$

$$\ln(0.04) = \ln(e^{-0.0300t})$$

$$\ln(0.04) = -0.0300t$$

$$\frac{\ln(0.04)}{-0.0300} = t$$

so

$$t \approx 107$$ minutes
